Horse: TR American Doll

Owner: Clint and Cally Kindred

The filly was evaluated for facial swelling. There is fibrous swelling on the dorsal aspect of the face in the region of the frontal/facial suture line. The swelling is firm and non-painful. This is common in young horses that receive direct trauma to the facial region that disrupts the suture line where the bones come together. This will remodel over time and should return to a normal appearance. If there is any residual swelling it is cosmetic in nature only, and will not affect performance. There are no fractures noted in the frontal bone.

Radiograph head: there is a single lateral medial view available for interpretation. There is soft tissue swelling over the dorsal aspect of the frontal bone just distal to the level of the frontal sinus. There is mild thickening of the underlying cortical bone. No fractures are noted. The sinuses are normal.

Radiographic impression: Soft tissue swelling over the dorsal aspect of the facial bone consistent with trauma and suture line irritation.
